

EP12

Evaluation of Qualitative, Binary Output Examination Performance

This guideline includes descriptions of the types of qualitative, binary output examinations and procedures for evaluating their performance.

A guideline for global application developed through the Clinical and Laboratory Standards Institute consensus process.

Clinical and Laboratory Standards Institute

Setting the standard for quality in medical laboratory testing around the world.

The Clinical and Laboratory Standards Institute (CLSI) is a not-for-profit membership organization that brings together the varied perspectives and expertise of the worldwide laboratory community for the advancement of a common cause: to foster excellence in laboratory medicine by developing and implementing medical laboratory standards and guidelines that help laboratories fulfill their responsibilities with efficiency, effectiveness, and global applicability.

Consensus Process

Consensus—the substantial agreement by materially affected, competent, and interested parties—is core to the development of all CLSI documents. It does not always connote unanimous agreement but does mean that the participants in the development of a consensus document have considered and resolved all relevant objections and accept the resulting agreement.

Commenting on Documents

CLSI documents undergo periodic evaluation and modification to keep pace with advances in technologies, procedures, methods, and protocols affecting the laboratory or health care.

CLSI's consensus process depends on experts who volunteer to serve as contributing authors and/or as participants in the reviewing and commenting process. At the end of each comment period, the committee that developed the document is obligated to review all comments, respond in writing to all substantive comments, and revise the draft document as appropriate.

Comments on published CLSI documents are equally essential and may be submitted by anyone, at any time, on any document. All comments are managed according to the consensus process by a committee of experts.

Appeal Process

When it is believed that an objection has not been adequately considered and responded to, the process for appeal, documented in the CLSI *Standards Development Policies and Processes*, is followed.

All comments and responses submitted on draft and published documents are retained on file at CLSI and are available upon request.

Get Involved—Volunteer!

Do you use CLSI documents in your workplace? Do you see room for improvement? Would you like to get involved in the revision process? Or maybe you see a need to develop a new document for an emerging technology? CLSI wants to hear from you. We are always looking for volunteers. By donating your time and talents to improve the standards that affect your own work, you will play an active role in improving public health across the globe.

For additional information on committee participation or to submit comments, contact CLSI.

Abstract

Clinical and Laboratory Standards Institute guideline EP12—*Evaluation of Qualitative, Binary Output Examination Performance* describes the categories of qualitative, binary output examinations and covers their performance evaluations for imprecision, including estimating C5 and C95, clinical performance (sensitivity and specificity), and stability and interferences.

Clinical and Laboratory Standards Institute (CLSI). *Evaluation of Qualitative, Binary Output Examination Performance*. 3rd ed. CLSI guideline EP12 (ISBN 978-1-68440-176-5 [Print]; ISBN 978-1-68440-177-2 [Electronic]). Clinical and Laboratory Standards Institute, USA, 2023.

The Clinical and Laboratory Standards Institute consensus process, which is the mechanism for moving a document through two or more levels of review by the health care community, is an ongoing process. Users should expect revised editions of any given document. Because rapid changes in technology may affect the procedures, methods, and protocols in a standard or guideline, users should replace outdated editions with the current editions of CLSI documents. Current editions are listed in the CLSI catalog and posted on our website at www.clsi.org.

If you or your organization is not a member and would like to become one, or to request a copy of the catalog, contact us at:

Foreword

In vitro diagnostic (IVD) examinations report either the value or the characteristics of a clinical property. Quantitative examinations (measurement procedures) measure and report the value of a property of clinical samples. Other examinations of clinical samples report characteristics of a property by placing them into two binary categories: unordered (nominal) and ordered (ordinal). This guideline covers qualitative examinations that, in the user's hands, provide binary (eg, yes or no, positive or negative), nominal outputs (see Appendix A for examples). These examinations span a wide range of medical laboratory specialties, medical purposes, measurement technologies, and types of reported results. A binary response is created based on:

- A device's internal continuous response and a cutoff to provide binary results
- Algorithmic decision-making techniques that detect whether an analyte is present
- In some cases, a yes or no output without the aid of instrumentation

The performance of an IVD examination should be assessed during and after its development, and its performance should be validated before any examination results are used to make clinical decisions. This guideline covers the development of qualitative, binary, results-reporting or output examinations (referred to as qualitative, binary examinations throughout) and is intended to promote uniformity in performance assessment among:

- Developers of qualitative, binary examinations for:
 - Designing and developing examinations
 - Establishing and validating examination performance based on how an examination is designed
- Laboratories that verify qualitative, binary examinations before they are placed into service
- Laboratories that develop their own qualitative, binary examination(s)

Many quantitative examinations provide measurand values in units plus a decision threshold that can be applied to obtain a binary interpretation (see examination examples in Appendix A). Although the binary output performance of these examinations can be determined using the methods described in this guideline, performance evaluations designed for quantitative methods provide more flexibility and have more power to detect differences in performance. Therefore, performance assessment of quantitative examinations should be based on the guidelines described in CLSI document EP19.¹

Overview of Changes

This guideline replaces the previous edition of the approved guideline, EP12-A2, published in 2008. Several changes were made in this edition, including:

- Expanding the types of procedures covered to reflect ongoing advances in laboratory medicine
- Adding protocols to be used by developers, including commercial manufacturers or medical laboratories, during examination procedure design as well as for validation and verification
- Adding topics such as stability and interferences to the existing coverage of the assessment of precision and clinical performance (or examination agreement)
- Moving most of the statistical details, including equations, to the appendixes

NOTE: The content of this guideline is supported by the CLSI consensus process and does not necessarily reflect the views of any single individual or organization.

KEY WORDS

binary reporting	negative likelihood ratio	precision
clinical sensitivity	negative predictive value	qualitative examination
clinical specificity	positive likelihood ratio	stability
interferences	positive predictive value	

Chapter ①

Introduction

Evaluation of Qualitative, Binary Output Examination Performance

1 Introduction

1.1 Scope

EP12 provides product design guidance and protocols for performance evaluation of the Establishment and Implementation Stages of the Test Life Phases Model of examinations (see CLSI document EP19¹). EP12 characterizes a target condition (TC) with only two possible outputs (eg, positive or negative, present or absent, reactive or nonreactive). EP12 is written for both manufacturers of qualitative, binary, results-reporting or output examinations (referred to as qualitative, binary examinations throughout) and medical laboratories that create laboratory-developed, binary examinations (both termed developers). These protocols are also intended to help users verify examination performance in their own testing environment. Performance evaluation of examinations that provide outputs with more than two possible categories in an unordered (nominal) set or that report ordinal categories are outside the scope of this guideline.

1.2 Background

It is often necessary to provide test method results that have binary outputs (eg, yes or no). Health care providers may want to order an examination to help determine whether a disease is present in a patient, an analyte is present in a sample, a woman is pregnant, or the results of a drug test are positive. The two primary evaluations used for such examinations are clinical performance (sensitivity and specificity) and precision.

Assessments of clinical performance during the establishment and validation of a binary categorization process are performed by examining samples from subjects with a known category (ie, TC present vs TC absent). Ideally this analysis involves the comparison of binary results for an intended-use population of samples from the candidate examination with an independent procedure that provides the best available assessment of TC. However, in many cases, this comparison of binary results is an evaluation of agreement to positive or negative results from a comparative examination that is not such an assessment procedure.

Qualitative examination determinants of imprecision depend on the idea of the values in a relevant scale where a binary examination declares a sample to be positive 5% of the time (C5) and 95% of the time (C95). Unlike clinical performance, the means of determining C5 and C95 are different depending on how the binary categorization is performed (see Subchapters 3.1.3 and 3.2).

Reagent stability and examination interferences are two other performance attributes of examination systems. Although both topics are covered in CLSI documents EP07² (interferences) and EP25³ (stability), there are several considerations unique to qualitative examinations that warrant additional coverage in EP12. See Subchapters 3.4 (stability) and 4.3 (interferences) for more information on these topics.

1.3 Standard Precautions

Because it is often impossible to know what isolates or specimens might be infectious, all patient and laboratory specimens are treated as infectious and handled according to “standard precautions.” Standard precautions are guidelines that combine the major features of “universal precautions and body substance isolation” practices. Standard precautions cover the transmission of all known infectious agents and thus are more comprehensive than universal precautions, which are intended to apply only to transmission of bloodborne pathogens.
